Package: coxrt (via r-universe)

September 10, 2024

Type Package

Title Cox Proportional Hazards Regression for Right Truncated Data

Version 1.0.2

Author Bella Vakulenko-Lagun, Micha Mandel, Rebecca A. Betensky

Maintainer Bella Vakulenko-Lagun

<bella.vakulenko-lagun@mail.huji.ac.il>

Description Fits Cox regression based on retrospectively ascertained times-to-event. The method uses Inverse-Probability-Weighting estimating equations.

`coxph.RT` *Fits Cox Regression Model Using Right Truncated Data*

Description

Estimates covariate effects in a Cox proportional hazard regression from right-truncated survival data assuming positivity, that is `P(lifetime>max(right) | Z=0)=0`.

Usage

```
coxph.RT(formula, right, data, bs = FALSE, nbs.rep = 500,
  conf.int = 0.95)
```

Arguments

`formula`	a formula object, with the response on the left of a ~ operator, and covariates on the right. The response is a target lifetime variable.
`right`	a right truncation variable.
`data`	a data frame that includes the variables used in both sides of `formula` and in `right`. The observations with missing values in one of the variables are dropped.
`bs`	logical value: if `TRUE`, the bootstrap esimator of standard error, confidence interval, and confidence upper and lower limits for one-sided confidence intervals based on the bootstrap distribution are calculated. The default value is `FALSE`.
`nbs.rep`	number of bootstrap replications. The default number is 200.
`conf.int`	The confidence level for confidence intervals and hypotheses tests. The default level is 0.95.

Details

When positivity does not hold, the estimator of regression coefficients will be biased. But if all the covariates are independent in the population, the Wald test performed by this function is still valid and can be used for testing partial hypotheses about regression coefficients even in the absence of positivity. If the covariates are not independent and positivity does not hold, the partial tests cannot guarantee the correct level of type I error.

Value

A list with components:

`coef`	an estimate of regression coefficients
`var`	covariance matrix of estimates of regression coefficients based on the analytic formula
`n`	the number of observations used to fit the model
`summary`	a data frame with a summary of fit:

- coef a vector of coefficients
- exp.coef exponent of regression coefficients (=hazard ratio)
- SE asymptotic standard error estimate based on the analytic formula derived in Vakulenko-Lagun et al. (2018)
- CI.L lower confidence limit for two-sided hypothesis H_0: $\beta_i = 0$
- CI.U upper confidence limit for two-sided hypothesis H_0: $\beta_i = 0$
- pvalue p-value from a Wald test for a two-sided hypothesis H_0: $\beta_i = 0$
- pvalue.H1.b.gr0 p-value from the Wald test for a one-sided partial hypothesis H_0: $\beta_i \leq 0$ based on the analytical asymptotic standard error estimate
- pvalue.H1.b.le0 p-value from the Wald test a for one-sided partial hypothesis H_0: $\beta_i \geq 0$ based on the analytical asymptotic standard error estimate

bs if the input argument bs was TRUE, then an output list also includes an element bs with statistics from the bootstrap distribution of estimated coefficients:

- num.bs.rep number of bootsrap replications used to obtain the sample distribution
- var estimated variance
- summary a data frame with a summary of bootstrap distribution that includes: SE, a bootstrap estimated standard error; CI.L, a quantile estimated lower confidence limit for two-sided hypothesis H_0: $\beta_i = 0$; CI.U, a quantile estimated upper confidence limit for two-sided hypothesis H_0: $\beta_i = 0$; CI.L.H1.b.gr0, a quantile estimated the limit for one-sided hypothesis H_0: $\beta_i \leq 0$; CI.U.H1.b.le0, a quantile estimated the limit for one-sided hypothesis H_0: $\beta_i \geq 0$.

coxph.RT.a0, coxrt, coxph

Examples

```
# loading AIDS data set
library(gss)
data(aids)
all <- data.frame(age=aids$age, ageg=as.numeric(aids$age<=59), T=aids$incu, R=aids$infe, hiv.mon =102-aids$infe)
all$T[all$T==0] <- 0.5 # as in Kalbfeisch and Lawless (1989)
s <- all[all$hiv.mon>60,] # select those who were infected in 1983 or later
# analysis assuming positivity
# we request bootstrap SE estimate as well:
sol <- coxph.RT(T~ageg, right=R, data=s, bs=FALSE)
sol
sol$summary # print the summary of fit based on the analytic Asymptotic Standard Error estimate
```

`coxph.RT.a0` *Fits Cox Regression with Adjustment for the Lack of Positivity*

Description

Estimates covariate effects in a Cox proportional hazard regression from right truncated survival data for a given value of `a0=P(lifetime>max(right) | Z=0)`. This probability reflects the chance of falling to the right of the upper bound of the support of the right truncation variable in the reference stratum where all the covariates are zero. Right truncation might result in a completely unobserved right tail of the distribution of the target lifetime. That means that it can happen there will be no "representatives" in a sample from the right tail. Ignoring this and using `coxph.RT` in general will result in biased estimation of regression coefficients, whereas `coxph.RT.a0` allows to account for this violation.

Usage

```
coxph.RT.a0(formula, right, data, a0 = 0, bs = FALSE, nbs.rep = 200,
  conf.int = 0.95)
```

Arguments

`formula`	a formula object, with the response on the left of a ~ operator, and covariates on the right. The response is a target lifetime variable.
`right`	a right truncation variable.
`data`	a data frame that includes the variables used in `formula` and in `right`.
`a0`	probability of falling into the unobservable region in the stratum of `Z=0`, i.e. `P(lifetime>max(right) | Z=0)`. By default `a0=0`, which is equivalent to assuming positivity.
`bs`	logical value: if TRUE, the bootstrap esimator of standard error, confidence interval, and confidence upper and lower limits for one-sided confidence intervals based on the bootstrap distribution are calculated. The default value is FALSE.
`nbs.rep`	number of bootstrap replications. The default number is 200.
`conf.int`	The confidence level for confidence intervals and hypotheses tests. The default level is 0.95.

Value

a list with components:

`convergence`	convergence code as returned by `BBsolve`. `convergence` > 0 means that the algorithm diverged and a solution was not found. `BBsolve` is used with a default parameters setting.
`coef`	a vector of estimated regression coefficients.
`var`	covariance matrix of regression coefficients, if the input argument `bs` was `TRUE`; `NULL`, otherwise.

n	the number of observations used to fit the model.
a0	plugged-in value of a0.
bs	if the input argument bs was TRUE, then an output list also includes an element bs with statistics from the bootstrap distribution of estimated coefficients:

- num.bs.rep number of successful bootsrap replications used to obtain the sample distribution
- var estimated variance of regression coefficients
- summary a data frame with a summary of bootstrap distribution that includes: coef, a vector of estimated regression coefficients; exp.coef, an exponent of regression coefficients (=hazard ratio); SE, a bootstrap estimated standard error; CI.L, a quantile estimated lower confidence limit for two-sided hypothesis H_0: $\beta_i = 0$; CI.U, a quantile estimated upper confidence limit for two-sided hypothesis H_0: $\beta_i = 0$; CI.L.H1.b.gr0, a quantile estimated the limit for one-sided hypothesis H_0: $\beta_i \leq 0$; CI.U.H1.b.le0, a quantile estimated the limit for one-sided hypothesis H_0: $\beta_i \geq 0$.

coxrt *A Package to Fit the Cox Regression from Right Truncated Data*

Description

The method assumes that truncation is independent of covariates, and of lifetime, and that there is no censoring. The method uses Inverse-Probability-Weighting estimating equations with stabilized weights, IPW-S and IPW-SA, as described in Vakulenko-Lagun et al. (2018). Currently the code allows only time-independent covariates.

Details

The **coxrt** package provides two functions: `coxph.RT` (IPW-S) that assumes positivity and `coxph.RT.a0` (IPW-SA) that allows for adjustment of estimation using plugged-in `a0`. The illustrative examples in these functions include analysis of AIDS latency data with age as a covariate, where the AIDS cases were retrospectively ascertained at June 30, 1986, and only those who developed AIDS by that time were included in the analysis (Kalbfeisch and Lawless, 1989).
